Structural basis for the modulation of plant cytosolic triosephosphate isomerase activity by mimicry of redox-based modifications

Eduardo Castro-Torres, Pedro Jiménez-Sandoval, Sergio Romero-Romero, Alma Fuentes-Pascacio, Laura M. López-Castillo, Corina Díaz-Quezada, D. Alejandro Fernández-Velasco, Alfredo Torres-Larios, Luis G. Brieba

Significance Statement

Reactive oxidative species (ROS) and glutathione regulate plant cytosolic triosephosphate isomerases (cTPI) by targeting two reactive cysteines that function as thiol switches. Here we present the structural basis for cTPI inactivation by ROS and *S*-glutathionylation regulation. Our structures show how *S*-glutathionylation protects AtcTPI from irreversible chemical modifications while re-routing carbon metabolism aimed to decrease oxidative stress.

Motors convert one form of energy into another. For biological motors, adenosine triphosphate (ATP) serves as chemical energy and its hydrolysis is coupled to conformational changes that exert mechanical force. ATP synthases reverse this process in a multistep process: first converting an electrochemical gradient to rotational kinetic energy, and then coupling rotation to formation of high-energy phosphodiester bonds. Murphy *et al.* investigated these energy changes in the dimeric mitochondrial F₁-F_o ATP synthase from *Polytomella* sp., a unicellular alga. They solved high-resolution cryo-electron microscopy structures of the ATP synthase complex, extracting 13 rotational substates. This collection of structures revealed that the rotation of the F_o ring and central stalk is coupled with partial rotations of the F₁ head. This flexibility may enable the head to better couple continuous rotation with discrete ATP synthesis events.

QC keeps on keeping on

Several protein quality control processes have been identified that monitor and remove misfolded or damaged proteins in the endoplasmic reticulum. Schmidt *et al.* asked whether additional pathways monitor proteins further along the secretory pathway in the Golgi complex and the endosome. They identified a degradation pathway in budding yeast cells associated with endosome and Golgi, which they named EGAD. EGAD extracts membrane proteins from the Golgi and endosomes, allowing them to become substrates for cytosolic proteasomal degradation. An important cellular substrate of this pathway is a protein called Orm2, which is involved in down-regulating sphingolipid biosynthesis. The selective degradation of Orm2 facilitates the homeostatic regulation of sphingolipid biosynthesis.

NEWS

NEW WEED KILLERS Bayer AG in Leverkusen, Germany, announced it will spend €5 billion over the next decade on research to develop weed-killing alternatives to its controversial, widely used herbicide glyphosate. Countries in Europe have been moving toward banning the product, and Bayer faces multimillion-dollar U.S. jury verdicts from lawsuits alleging that it caused illnesses.

AGENCIES MOVED The U.S. Department of Agriculture has picked the Kansas City, Missouri, region to host two research units that many scientists say should be kept in Washington, D.C. “[Agriculture] Secretary [Sonny] Perdue is well on his way to dismantling one of the best agricultural economics research institutions in the world,” says Ron Wasserstein of the American Statistical Association in Alexandria, Virginia, about one of the units, the Economic Research Service. The other is the National Institute of Food and Agriculture.
