The human body is teeming with microorganisms that protect us from pathogenic infections, train our immune system, and play a major role in our digestive tract. To understand these complex microbial communities, it is crucial to elucidate the functions encoded by the genomes of these microbes. This is no trivial task: even the initial step of identifying coding genes from metagenomic sequences can be challenging, especially when searching for particularly small genes (15–150 nucleotides). Most standard prediction tools discard such genes, as they are harder to detect without inflating the number of false-positive predictions ([Housman and Ulitsky, 2016](#), [Makarewich and Olson, 2017](#), [Saghatelian and Couso, 2015](#)). Nevertheless, the significance of small proteins should not be understated, as they take part in key processes in all clades of the tree of life, from phages to mammals. In bacteria, their functions encompass spore formation, quorum sensing, mediation of the stress response, regulation of signaling pathways, antimicrobial activity, and protein translation ([Baumgartner et al., 2016](#), [Miravet-Verde et al., 2019](#), [Weaver et al., 2019](#)). In this issue of *Cell*, [Sberro et al. \(2019\)](#) performed a large-scale study seeking small protein-coding genes encoded by the human microbiome. By considering conservation, phylogenetic distribution, signature sequences, and genomic context, they reveal thousands of small protein families. Most of these proteins have never been described before and could have far-reaching effects on our microbiome.
